'« Zezwal', 'next' => '» Kiwi',); Antigen-binding properties of anti-Ia IgG2a monoclonal antibodies. To investigate the role of a cytoplasmic polypeptide (AgI) shared by B lymphocyte and monocyte/macrophage differentiation, two types of IgG2a anti-AgI monoclonal antibodies (mAb) were characterized. The mAb, MA-1 and MA-2, bind independently of each other to AgI expressed by a permanently activated B lymphocyte cell line, B1C1. They also bind in vivo to the cytoplasm of mouse lymphocytes and monocytes/macrophages and are detected in the sera of mice immunized with AgI. The specificity of these mAb for AgI was analyzed by solid-phase binding, inhibition of binding, and inhibition of AgI-induced T cell proliferation. mAb MA-1, which recognizes a conformationally distinct part of AgI, inhibited the binding of the second mAb, MA-2, to the same portion of AgI. In addition, MA-1 was able to inhibit the T cell proliferative response of T cells to AgI-pulsed macrophages, and the mAb bound to the surface of AgI-activated T cells. In contrast, mAb MA-2, which binds in an overlapping conformation with MA-1, did not inhibit T cell proliferation in response to AgI-p 82157476af
