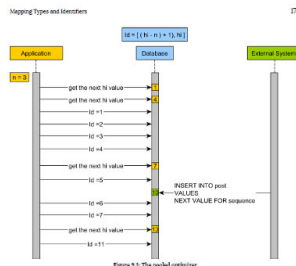

Figure 9.3 The pooled optimizer

If increment size (n) is the number of identifiers within a range, the pooled optimizer will generate identifiers with the following formula: $id = (id - n) + (n * i)$.

- The first sequence call generates the hi value and the second one determines the hi value, so the first range of identifiers is (2, 3, 4).
- When adding the 3th entry, the pooled optimizer calls the sequence again and obtains the next hi value, the next identifier range being (5, 6, 7).
- After inserting the 3th entry, an external system adds a post row and assigns the primary key with the value returned by the sequence call.
- The Hibernate application the read resumes and inserts the identifiers 6 and 7.
- The 3th entry requires a new sequence call, and so a new range is allocated (11, 12, 13).

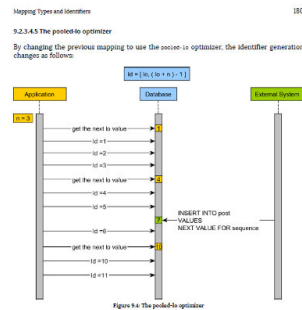

Figure 9.4 The pooled-to optimizer

If increment size (n) is the number of identifiers within a range, the pooled-to optimizer will generate identifiers with the following formula: $id = (id - n) + (n * i)$.

- The first sequence call generates the hi value, so the first range of identifiers is (1, 2, 3).
- When adding the 3th entry, the pooled-to optimizer calls the sequence and obtains the next hi value, the next identifier range being (4, 5, 6).
- After inserting the 3th entry, an external system adds a post row and assigns the primary key with the value returned by the sequence call.
- The Hibernate application the read resumes and inserts the identifier 6.
- The 7th entry requires a new sequence call, and so a new range is allocated (10, 11, 12).
